Such condition is possible and is satisfied only by the very steep potentials. Therefore, we can anticipate a radically different behavior if we include the effects of the Gaussian couplig: this new deep potential may reduce considerably the anomalous motion. This result has been checked starting from the following Hamiltonian $H = -\frac{1}{2} \frac{\partial^2}{\partial x^2} + \gamma \exp(-x^2)$ which leads to: $\frac{E_n}{E_{\text{e}}} = \frac{n^2}{2} + \frac{1}{2} \left[1 + \frac{a}{n} \left(2 + \sqrt{1 + \gamma^2} \right) \right]$ In Fig. [fig1] the calculated values of the energy ratio are compared with the corresponding experimental values. A great improvement is found, particularly for the $a=0$ case. The potential ([Hnew]) has a minimum at $x=0$, what seems to be a strange feature, however it is perfectly possible and it is not forbidden by principle. [(color online) The comparison between the theoretical results ([FINAL]) and the experimental values for E_n/E_{e} . Here the square root in the factor a/n of Eq. ([FINAL]) has been substituted by its argument.]{data-label="fig1"}(fig1.eps){width="0.65\linewidth"} The remaining problem is the prediction of the γ value which is the cornerstone of the general argument. We have solved numerically the Hamiltonian
